Tissue Pricer — How to Use It

1. 

2. What it is
   - The tissue price is the model's estimated win probability for each runner.
     - It is calculated independently from bookmaker and exchange odds.
     - Represents the model's own opinion before market odds are checked.
   - Provides a comparison between your price (model) and the market price.
   - Importance: Acts as an independent judge to spot value when the market might be wrong.
   - Note: Cards are segmented by race type (e.g., NON-HANDICAP label at top-left).

3. Reading the card — column by column
   - Saddlecloth or runner number.
   - HORSE
     - Name plus tags (e.g., GB+DB for Going and Draw bias).
     - Jockey and trainer details shown beneath.
   - SCORE — Model's overall composite rating for the runner.
   - TISSUE
     - Model's fair price.
     - Sortable; default sorting is by Tissue ascending.
   - EXCH — Current exchange price for comparison.
   - IMPL%
     - Implied probability shown in two ways:
       - T = Tissue implied % (model's probability).
       - E = Exchange implied % (market's probability).
     - Value is found in the gap between T and E — model probability above the market.
   - EDGE%
     - Headline value figure representing discrepancy between model and market.
     - Positive value: model rates the horse better than the market (potential value).
     - Negative value: market rates it shorter than the model (likely no value).
   - BREAKDOWN
     - Colour-coded signal chips showing strengths and weaknesses.
     - Green = strong signal, Red = weak signal.

4. Decoding the BREAKDOWN chips
   - RTG — rating
   - FRM — form
   - TRN — trainer
   - JKY — jockey
   - GNG — going suitability
   - C/D — course & distance record
   - DST — distance suitability
   - FIT — fitness / readiness
   - CAR — career record
   - DRW — draw

5. Spotting value (the core skill)
   - Focus first on EDGE%:
     - Positive EDGE% numbers indicate value picks by the model.
   - Cross-check Tissue vs Exchange implied percentages (IMPL%):
     - A positive T-over-E gap flags potential value — but the largest EDGE% figures are usually longshots, where the maths inflates a small gap. Investigate, don't assume.
   - Value edge is strongest with mid-priced runners (BSP approximately 8–50).
   - Mind the sort order:
     - Default is by Tissue price, so highest EDGE% may not be on top.
   - Caution:
     - Value is an edge over many bets, not a single-race certainty, an edge merely implies value.

6. Reading the chips alongside the edge
   - A high EDGE% supported by green chips in GNG, C/D, or DST is a stronger signal.
   - A high EDGE% undermined by red TRN or FRM chips calls for caution.
   - Use the breakdown chips to understand why the model favors or doubts a runner.

7. Putting it into action
   - Identify a runner with a positive EDGE%.
   - Sanity-check breakdown chips and contextual factors, such as going and draw.
   - Size each bet sensibly using tools like the Bet Calculator.
   - Record your bets and regularly review performance to compound value over time.

8. Common mistakes to avoid
   - Treating Tissue or IMPL% as a guaranteed winner prediction rather than a probability.
   - Backing short-priced runners outside the edge zone.
   - Reading only EDGE% while ignoring the detailed breakdown chips.
   - Assuming the top row is always the best bet—check how the card is sorted.
   - Chasing a single good result rather than trusting the value betting process.

9. Where to go next
   - Learn more about the value betting framework and concepts in the book *Mispriced*.
   - The book explains how horse racing markets work and how to beat them through value betting.
